### Goal

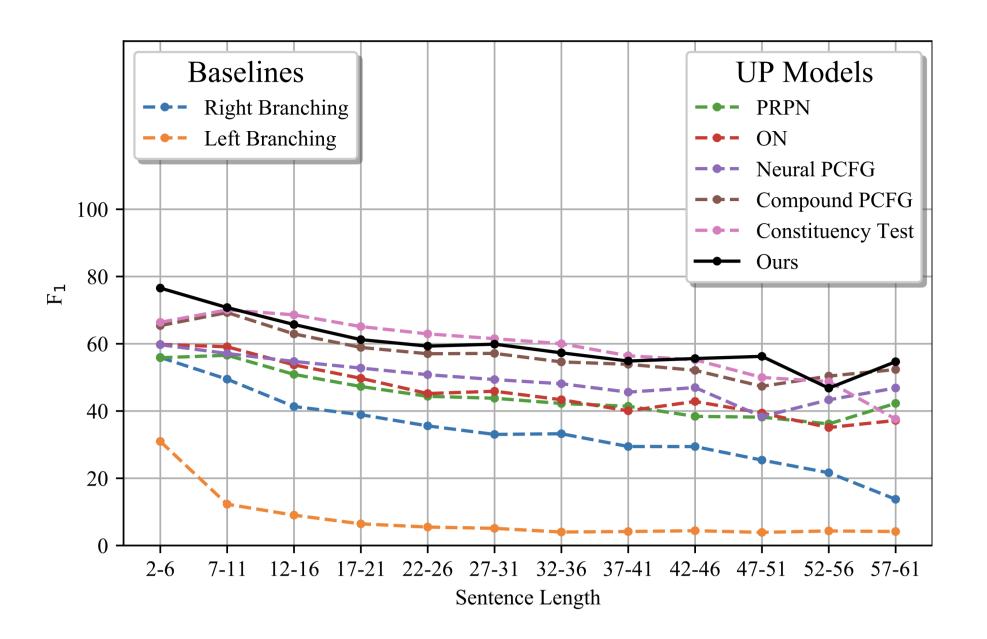

Induce parse trees from observed sentences alone without supervision.

### Motivation

We use semisupervised and weaklysupervised learning techniques to induce latent trees and achieve state-of-the-art results on three treebanks.

5. Retrieve the outside strings from the most confident insides and train the outside classifier.

## F1 vs. Sentence Length Plot

### **PTB Results**

Model

|  | IN |
|--|----|
|--|----|

- Current supervised parsers operate on a minuscule of commonly spoken languages in the world.
- The process of annotation of syntactic trees by human language experts is often associated with high-costs and is time-intensive.
- Lack of clear annotation rubrics for certain low-resource languages.
- Annotations lack ability to scale to out-of-domain data.

## **Proposed Approach**

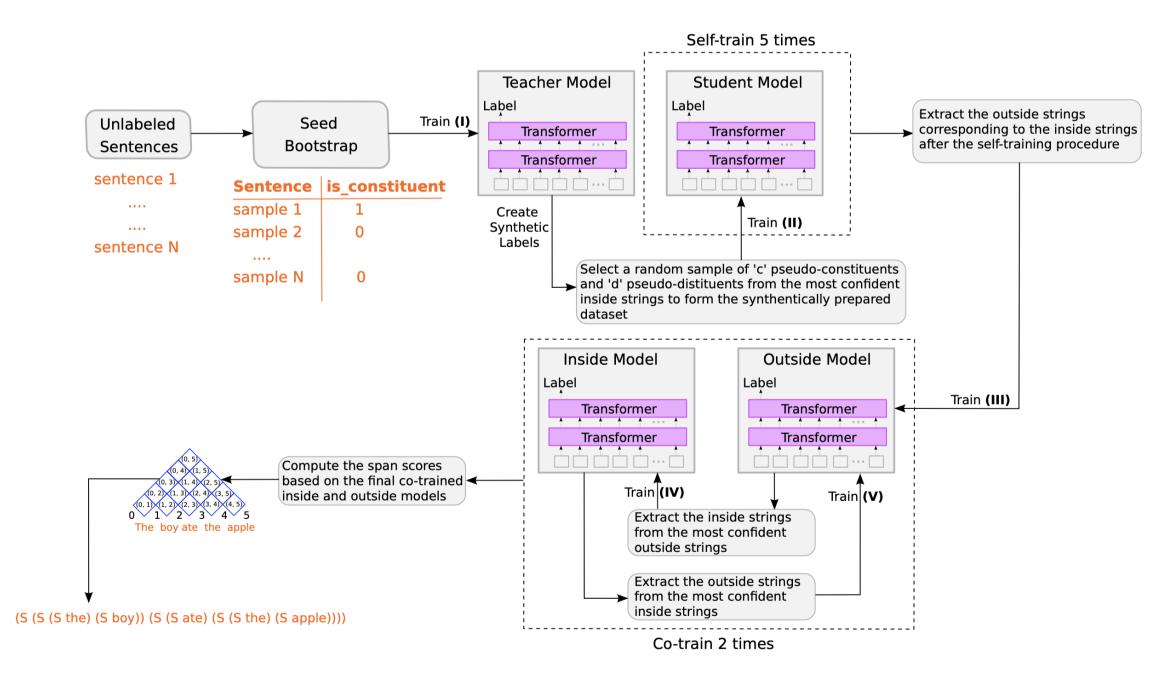

- We formulate the task of identifying constituents and distituents (referring to spans that are not constituents) in a sentence as a binary classification task by devising a **seed bootstrapping** strategy to convert the unlabeled data into a classification task.
- We build a sequence classification model by fine-tuning a Transformer-based PLM on the unlabeled training sentences to distinguish between the true and false **inside** strings of constituents.

| Oracle Binary Trees                            | 81.1 |      |  |

- We use the highly-confident inside strings to produce the outside strings.
- Through the use of semi-supervised learning techniques, i.e., **self-training** and **co-training**, we jointly use both the inside and outside passes to enrich the model's ability to determine the breakpoints in a sentence.

We perform the self-training procedure for five iterations which follow multiple steps:

| Upper Bound                                    | 76.5 |               | 76.6 |               |  |

- 1. Fine-tune a RoBERTa (base) model (teacher) on a downstream task using a cross-entropy loss after seed bootstrapping.
- 2. Synthetically annotate this data using the teacher model and select top K samples corresponding to each class to form the final synthetic dataset; We fine-tune a RoBERTa (base) model (student) on this dataset using hard labels and retrieve the outside strings from the most confident insides.
- 3. Train the outside classifier on these outside strings; We perform the co-training procedure for two iterations which follow a two-fold optimizing step.
- 4. Retrieve the inside strings from the most confident outsides and train the inside classifier.

- Our parser has the ability to generalize to languages of known branching direction (left/right) and achieves new state-of-the-art-results on three treebanks comprising both right- and left-branching languages.
- The use of inside and outside strings (inspired by the notion of inside and outside trees for the spectral learning of latent-variable PCFGs) is a crucial component in our pipeline.
- Employing semi-supervised learning techniques to model interactions between the inside and outside classifiers results in an overall improved parsing performance.
